ESP = Energy Service Provider

A Comprehensive Solution

- Standards could apply utility-grade security to individual HAN messages
 - Current security credentials
 - Apply to all communications of all devices on a logical network
 - Logical and physical network are treated as one (at least in most current implementations)
 - Thus for one device to talk to another they must be registered on the same logical network
 - Potential solution (on a single logical/physical HAN)
 - Most messages: utilize existing wireless network security
 - Messages requiring higher security, privacy or confirmation: additional SEP-level security is applied at low level in the stack
 - Could be based on one or more of: specific message; message type; source/destination pair
 - Utility-controlled devices must support this higher security but inexpensive dimmers, etc, would not need to
 - This solves all stated issues but would be a significant architectural change
